SOLUTION PITCH

GramSetu

Speak your language. The form gets filled with you, and submits only when you say so.

A voice-first agent for government and healthcare web services in Kannada, Hindi, Tamil and English, built on Gnani Prisma and Timbre.

The problem

A farmer applying for a support scheme, or a patient booking a clinic visit, can explain exactly what they need out loud. What stops them is the screen: English-first forms, field after field, where one small mistake means starting again. Getting help often means depending on someone else and handing over personal details.

The solution

GramSetu ("bridge to the village") turns a spoken request into a completed online form, in three steps:

1. Speak

Say it naturally. Gnani Prisma writes it down in your own script so you can check the words.

2. Review

GramSetu fills what it understood. Gnani Timbre asks aloud only for what is missing or unclear, then reads back a summary.

3. Watch it work

After you approve, a browser agent fills the portal while you see every step, and the result is read out to you.

How Gnani powers it

- **Prisma** (speech-to-text) transcribes each turn in the user's language and script.
- **Timbre** (text-to-speech) speaks every question, summary and result.
- Both verified live in all four languages, with caching, a usage guard and a per-turn latency display.

Built for trust

- Nothing is typed before you approve, and the final submit needs a second yes.
- One-time codes go from your hand to the portal, never to logs, models or speech.
- "Done" is said only after the portal's stored record is found.

What is built and measured

Two complete workflows: a PM-KISAN-style scheme application and clinic booking with no double booking. The agent reads a portal's validation errors and corrects itself.

33/33	39/39	12/12	2/2	60
Requests understood	Fields extracted	Unsafe actions blocked	Workflows verified end to end	Automated backend tests pass

Measured on the project's own test set with synthetic audio.

Who it helps, and how it scales

Farmers, patients, older adults and first-time internet users, along with the family members and service-centre staff who assist them. Today GramSetu runs on built-in practice portals with sample data, using a deterministic understanding engine behind a pluggable provider interface. An adapter framework lets each new service plug in, with trials among real speakers and a security review before any official portal is connected.
